Statistical Natural Language Processing

Recurrent and convolutional networks

Çağrı Çöltekin

University of Tübingen Seminar für Sprachwissenschaft

Summer Semester 2020

Why deep networks?

- We saw that a feed-forward network with a single hidden layer is a universal approximator
- However, this is a theoretical result it is not clear how many units one may need for the approximation
- Successive layers may learn different representations
- · Deeper architectures have been found to be useful in many

Ç. Çöltekin, SfS / University of Tübingen

Summer Semester 2020 2 / 27

Deep ANNs RNNs CNNs

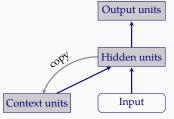

Recurrent neural networks

- Feed forward networks
 - can only learn associations
 - do not have memory of earlier inputs: they cannot handle
- Recurrent neural networks are ANN solution for sequence learning
- This is achieved by recursive loops in the network

Ç. Çöltekin, SfS / University of Tübingen

Deep ANNs RNNs CNNs

A simple version: SRNs Elman (1990)

- The network keeps previous hidden states (context units)
- The rest is just like a feed-forward network
- Training is simple, but cannot learn long-distance dependencies

Deep neural networks

 Deep neural networks (>2 hidden layers) have recently been

- successful in many tasks They often use sparse connectivity and shared weights
- We will focus on two important architectures: recurrent and convolutional networks

Ç. Çöltekin, SfS / University of Tübinge

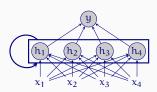

Why now?

- Increased computational power, especially advances in graphical processing unit (GPU) hardware
- · Availability of large amounts of data
 - mainly unlabeled data (more on this later)
 - but also labeled data through 'crowd sourcing' and other
- Some new developments in theory and applications

Ç. Çöltekin, SfS / University of Tübingen

Summer Semester 2020 3 / 27

Recurrent neural networks

- · Recurrent neural networks are similar to the standard feed-forward networks
- They include loops that use previous output (of the hidden layers) as well as the input
- Forward calculation is straightforward, learning becomes somewhat tricky

Ç. Çöltekin, SfS / University of Tübingen

Deep ANNs RNNs CNNs

Processing sequences with RNNs

- RNNs process sequences one unit at a time
- The earlier inputs affect the output through recurrent links

C. Cöltekin. SfS / University of Tübingen Summer Semester 2020 6 / 27

Note: the weights with the same color are shared.

Deep ANNs RNNs CNNs

Learning in recurrent networks

- We need to learn three sets of weights:
 W₀, W₁ and W₂
- Backpropagation in RNNs are at first not that obvious
- The main difficulty is in propagating the error through the recurrent connections

Unstable gradients

- A common problem in deep networks is unstable gradients
- The patial derivatives with respect to weights in the early layers calculated using the chain rule
- A long chain of multiplications may result in
 - vanishing gradients if the values are in range (-1,1)
 - $-\ \emph{exploding gradients}$ if absolute values larger than 1
- A practical solution for exploding gradients is called *gradient clipping*
- Solution to vanishing gradients is more involved (coming soon)

Deep ANNs RNNs CNNs

Unstable gradients revisited

- We noted earlier that the gradients may vanish or explode during backpropagation in deep networks
- This is especially problematic for RNNs since the effective dept of the network can be extremely large
- Although RNNs can theoretically learn long-distance dependencies, this is affected by unstable gradients problem
- The most popular solution is to use *gated* recurrent networks

Convolutional networks

Gated recurrent networks

• Most modern RNN architectures are 'gated'

Deep ANNs RNNs CNNs

- · The main idea is learning a mask that controls what to remember (or forget) from previous hidden layers
- Two popular architectures are
 - Long short term memory (LSTM) networks (above)
 - Gated recurrent units (GRU)

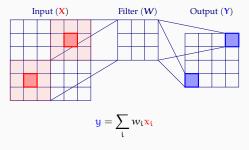

• Convolutional networks are particularly popular in image

- processing applications
- $\bullet\,$ They have also been used with success some NLP tasks
- Unlike feed-forward networks we have discussed so far,
 - CNNs are not fully connected
 - The hidden layer(s) receive input from only a set of neighboring units
 - Some weights are shared
- A CNN learns features that are location invariant
- CNNs are also computationally less expensive compared to fully connected networks

Deep ANNs RNNs CNNs

Convolution in image processing

- · Convolution is a common operation in image processing for effects like edge detection, blurring, sharpening, ...
- The idea is to transform each pixel with a function of the local neighborhood

Ç. Çöltekin, SfS / University of Tübingen

Example convolutions

Blurring

$$\frac{1}{16} \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$$

• Edge detection

$$\begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$$

Ç. Çöltekin, SfS / University of Tübingen

Deep ANNs RNNs CNNs

Learning convolutions

- Some filters produce features that are useful for classification (e.g., of images, or sentences)
- In machine learning we want to learn the convolutions
- Typically, we learn multiple convolutions, each resulting in a different feature map
- · Repeated application of convolutions allow learning higher level features
- The last layer is typically a standard fully-connected classifier

Ç. Çöltekin, SfS / University of Tübingen

Convolution in neural networks

χ1 χ_2 **X**3 **x**5

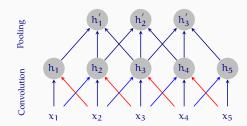

- Each hidden layer corresponds to a local window in the
- · Weights are shared: each convolution detects the same type of features

Ç. Çöltekin, SfS / University of Tübingen

Deep ANNs RNNs CNNs

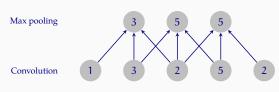

Deep ANNs RNNs CNNs

Pooling

- Convolution is combined with pooling
- Pooling 'layer' simply calculates a statistic (e.g., max) over the convolution layer
- · Location invariance comes from pooling

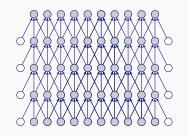

Pooling and location invariance

· Note that the numbers at the pooling layer are stable in comparison to the convolution layer

Padding in CNNs

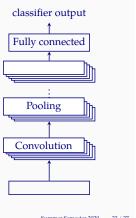

- With successive layers of convolution and pooling, the later layers shrink
- One way to avoid this is padding the input and hidden layers with enough number of zeros

Ç. Çöltekin, SfS / University of Tübingen

CNNs: the bigger picture

- · At each convolution/pooling step, we often want to learn multiple feature maps
- · After a (long) chain of hierarchical feature maps, the final layer is typically a fully-connected layer (e.g., softmax for classification)

C. Cöltekin, SfS / University of Tübingen

Real-world examples are complex

really

The real-world ANNs tend to be complex

- Many layers (sometimes with repetition)
- Large amount of branching

An example: sentiment analysis

Pooling

Feature maps

Convolution Word vectors Input

CNNs in natural language processing

 $\bullet\,$ The use of CNNs in image applications is rather intiutive

Deep ANNs RNNs CNNs

- the first convolutional layer learns local features, e.g., edges

- In NLP, it is a bit less straight-forward

 - CNNs are typically used in combination with word vectors
 The convolutions of different sizes correspond to (word) n-grams of different sizes
 - Pooling picks important 'n-grams' as features for classification

Ç. Çöltekin, SfS / University of Tübingen

Summary

- Deep networks use more than one hidden layer
- Common (deep) ANN architectures include: CNN shared feed-forward weights, location invariance RNN sequence learning
